

Agenda & Objectives

- Understand System workload
- Collecting workload statistics
- Distinguishing load from effect
- Load patterns and dimensions
- Correlation between load-factors
- Putting workload characteristics to use
- Stress Tests- A New Approach

Overview Of Workload

- What is system workload?
- How is a system's workload influenced?
- Why should we characterize a system's workload?

What is System Workload?

The demand placed on a system's resources in order to do the assigned work can be defined as workload. In a database system, the demand arises from queries and transactional requests (commits and rollbacks), whose conglomerate could be observed in terms of CPU, Memory and I/O related resource consumption or usage.

A few "influential factors" -

- End users and their behavior- intensity with which work is done
- Concurrency of online users and the mix of the programs they are executing
- Nature of the End-user layer of the application like various Forms, canned reports vs. Parameterized Reports, etc.
- Application execution architecture- multiple tiers, proxy serviceability, threads of execution, serial vs. parallel execution, etc.
- Security and audit features
- Layers, levels and sizes of caching- at Oracle, OS, Disk system, Network(JDBC caching), App server(JAVA caching), web server(HTTP Caching), client cache, etc.
- Data models and nature of the data like volatility, reuse, currency, READ vs. READ-WRITE nature of business transactions, etc.

Why Characterize system Workload?

Capacity & Performance Planning haracterization

Work Load

Load & Performance Modeling

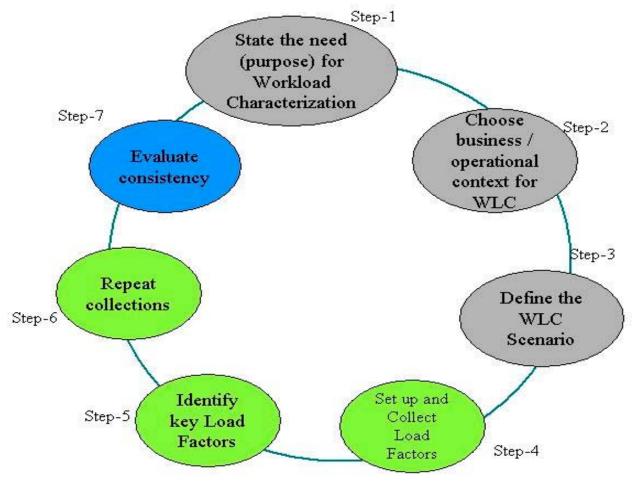

Future Performance Prediction

Performance Tuning

Statistics Collection

Tactical issues with statistics collection

Tactical Issues in Collecting Statistics

Source of Statistics

- Some common views that provide database statistics are:
 - v\$sysstat,
 - v\$sesstat,
 - v\$sgastat,
 - v\$pgastat,
 - v\$rollstat,
 - v\$undostat,
 - v\$filestat,
 - v\$latch and
 - v\$session_wait.

Load and Effect

Load and its Dimensions:

- Oracle system statistics reflect and represent system load.
- Workload in a system essentially is multi-dimensional and is a complex non-linear addition of them.

Load Effects:

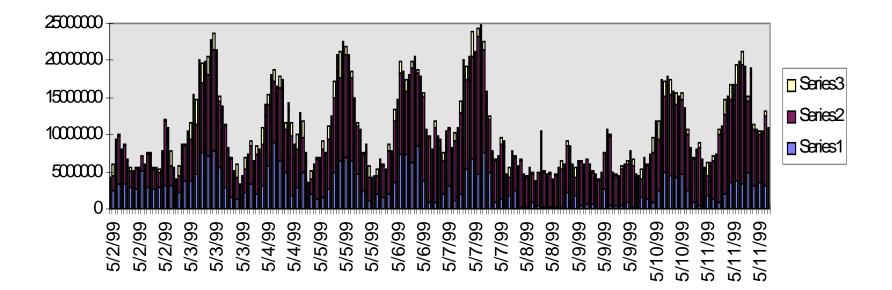

- Oracle wait events are significant in observing the resultant effects on the system under a given load.
- The types of queues and amount of waiting will fall into different categories (enqueues, child latches, etc.) and will also vary in terms of waited time (nanoseconds to microseconds to seconds.

Environment Specific Waits

- An OLTP database will predominantly spend most of its time waiting on certain specific resources (latch free, log file sync, db file scattered read etc.)
- These may be different for a data warehouse (DWH) where parallel query waits are more common (PX Deq: Execute Reply, PX Deq: Execution Msg etc.).

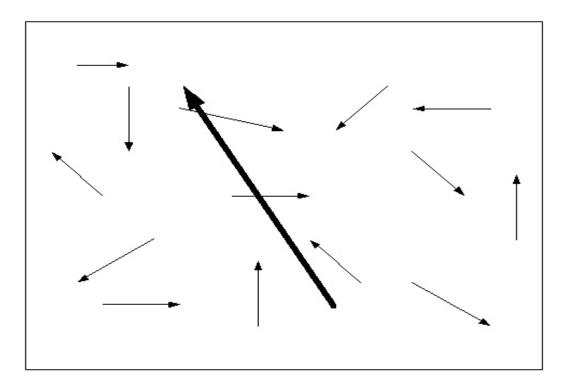

Load Patterns

Intensity of Physical Reads during the course of a day

Meaningful Correlation Between Load-factors

Vectors in a vector space—Example 1

Meaningful Correlation Between Load-factors

Vectors in a vector space—Example 2.

Identifying Relationships

Based on work :

DBWR related activity PHYSICAL Writes DB Block changes REDO activity UNDO segment activity Transaction table writes.

Based on a class of work (Ex. Class #2):

redo blocks written redo entries redo log space wait time redo size redo synch writes redo write time redo writes redo buffer allocation retries redo log space requests redo ordering marks redo synch time redo wastage redo writer latching time

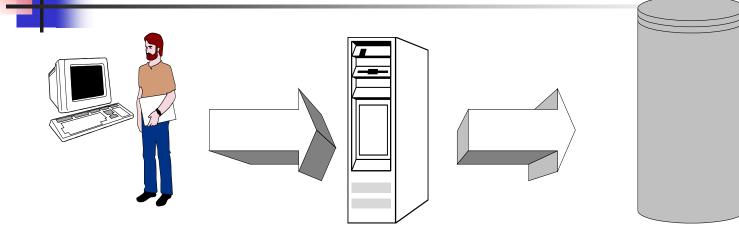

Regression Analysis to Determine Relationships-1

- Statistical regression modeling
 - helps to build a mathematical model based on cause and effect.
- Traditional Variance analyses
 - are inappropriate to analyze a complex system such as an Oracle database, which has layers of functionality. These layers represent different technical operational structures are independent but at times follow a daisy chain like activity-precedence approach.

Regression Analysis to Determine Relationships-2

- Independence and Interindependence
 - Independence is prevalent (consistency management, bulk or highly selective index fetching) at the same time as Interdependence (physical disk reads as a result of failure to cache a data block)
- Oracle load-factors exhibit both:
 - determinism
 - spontaneity
- Model Strength
 - quantified through the R-Squared value of the regression model

The Scaling Model- Regression

Users and Work-stations growth PLUS Application behavior PLUS User behavior on the work-station = Active user proxy variable

and queueing of resources ultimately determining the various counters in t he DB reflecting as System-Statistics

10-12 DRIVERS that

drive the consumption

100 other statistics in Oracle DB that are mutidimensional representations of the

data server load

Use of Log Values-1

- Linear and non-linear relationships
 - relationships are not always linear due to their complex interactions
- Non-linear relationships
 - Require non-linear regression techniques
 - Use of log values

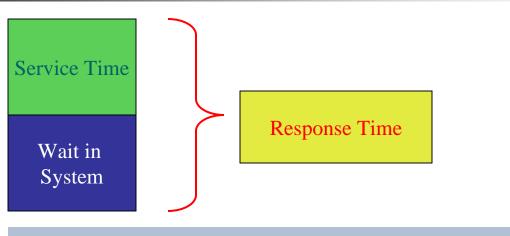

Use of Log Values-2

- Logarithmic values of the variable reduce the nonlinearity to linearity between log predicates
- Non-linear models are more reliable because they address both:
 - linear
 - non-linear behavior

Developing Capacity Models

Distinguish Between Work Load and Wait Events

- Service Time is a conglomerate of 'inescapable', networked response times
- This is the minimum time from the most optimal 'way' the work [eg: FTS vs. Index Scans]

Time Window ÷ Response Time = Work Done (Throughput)

QT to the Rescue

- Queuing Theory
 - Universal Applicability
 - Grocery store to Computer Science
 - Considerable research and publications
 - Queues form because of finite resources

QT- Foundations

- Queueing Theory
 - Essential Components of Queues
 - λ The Arrival rate of jobs into the system
 - μ The service rate at a resource counter
 - U The utilization of the resource
 - Fundamentally,
 - U = λ/μ
 - $\lambda/\mu < 1$, Queue builds up
 - Response time (R) = 1 / [μ (1 U)]

QT- Types of Queues

- Types Of Queues
 - M/M/m Random Arr, Svc, m- counters
 - M/M/1
 - M/M/∞
 - M/M/m/B Buffrd jobs, no Arr beyond 'B'
 - G/G/m Known rates, like Mfg systems

MVA—Mean Value Analysis

- What is MVA?
 - Simplified determination of queue behavior and ignores variances in response times.
 - Adopts and iterative computational algorithm
 - Closed queues assumed

MVA—Mean Value Analysis

Formulas

- N number of jobs or users in the system.
- m number of devices in the queue system
- Z think time
- S_i is the service time at ith device
- V_i is the number of visits to the ith device
- X system throughput = N / (Z + R)
- R Response time $=_1 \sum^m (R_i * V_i)$
- $R_i R$ at ith device = $S_i * (1+Q_i)$
- Q_i jobs in the queue at ith device = X * V_i * R_i

MVA—Mean Value Analysis

Algorithm

```
Initialize the run for i = 1 to m with Q_i = 0;

FOR n = 1 to N LOOP

BEGIN

For i = 1 to m LOOP

R_i = \sum S_i * (1 + Q_i)

R = {}_1 \sum^m (R_i * V_i)

X = N / (Z + R)

For i = 1 to m

Q_i = X * V_i * R_i

END

Throughput at ith device X_i = X * V_i and
```

Utilization $U_i = X * S_i * V_i$

- Objective
 - System Response time and throughput comparison before and after tuning.
 - Identification of system bottlenecks and scalability.
- Assumptions
 - Transactions characterize load and in turn load causes resource consumption and queue formation

- Top wait events
 - before tuning
 - enqueue
 - db file sequential read
 - latch free
 - After tuning
 - db file sequential read
 - db file scattered read
 - latch free

Wait befor tuning	total waits	time in sec
enqueue	18,208	55,340
db file sequential read	4,106,472	17,412
latch free	17,111,757	9,520

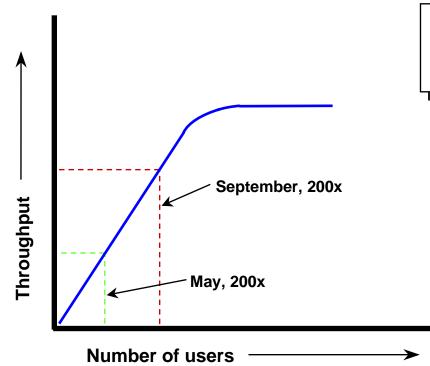

Wait after tuning	total waits	time in sec
db file sequential read	6,465,304	5,548
db file scattered read	8,201,125	3,584
latch free	202,955	2,514

Data Server Load Testing-An Augmented Method

Goals: Scalability Projection

Scaling tests predict resource requirements to support anticipated loads.

Goals – Validate Success Initiatives

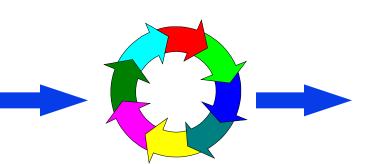

New Initiatives

New Application Design & Development

Application Upgrade Design & Planning

Planned Enterprise Architecture Change/Upgrade

Application/Server Patch Implementation

Performance-Based Analysis

Performance Analysis

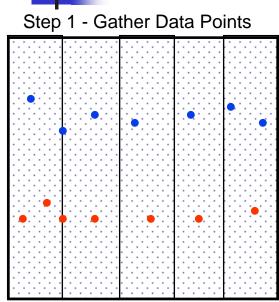

Current server config will support xxx users

Application is CPU bound at yyy users

Planned patch decreases I/O throughput by xx%

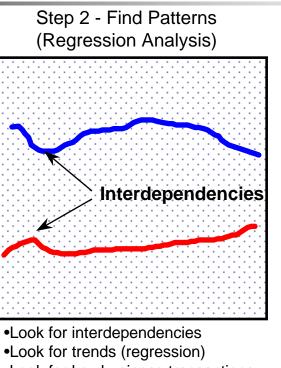

Planned architecture will require xxx server platforms per 5,000 users

Summary

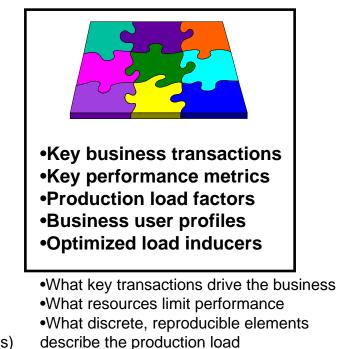

Measure full suite of Oracle parameters
Measure at key production windows
Measure before/after transactions

•Snapshot of actual production workload

- •Look for key business transactions
- •Determine "knee" points (break points)

Step 3 - Define and Deploy Production Load Profile

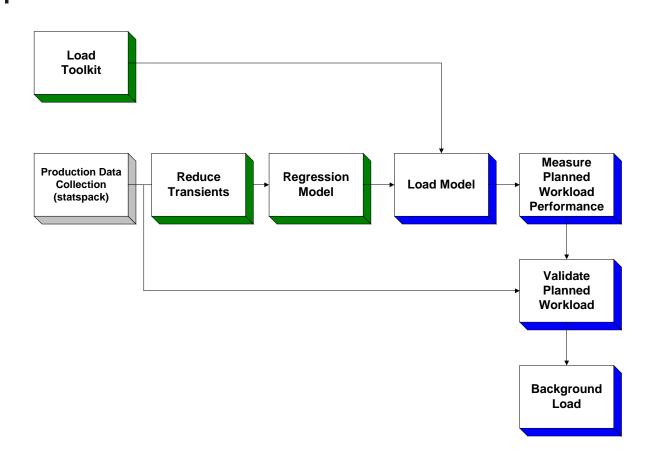

•Use specific load factors to do testing

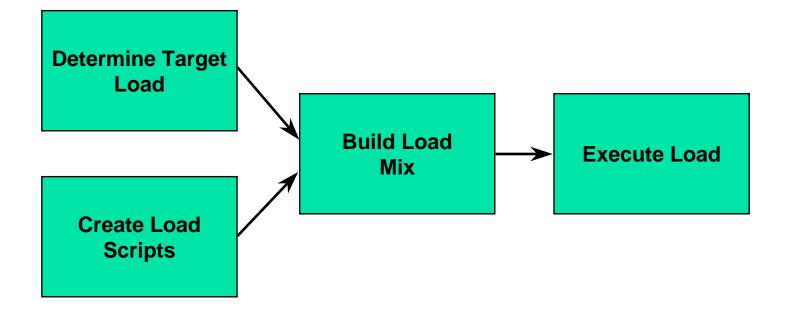

Three Phases :

- 1. Assessment gather data points, interview business users
- 2. Analyze and test data. Regression analysis. Optimize load factors
- 3. Deploy load profile to answer business questions scaling, sizing, performance

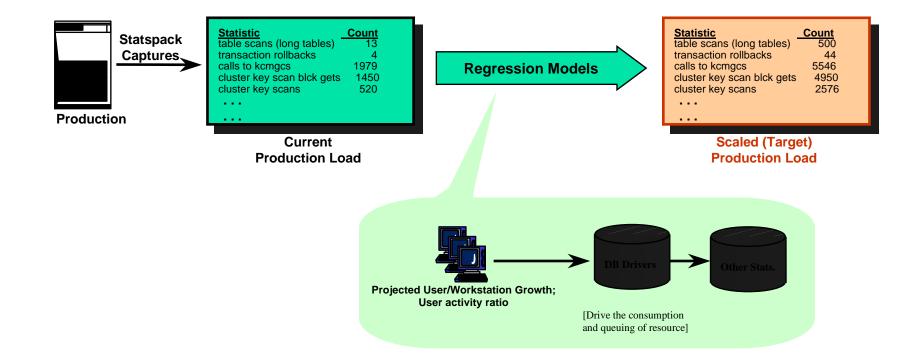

Process Flow

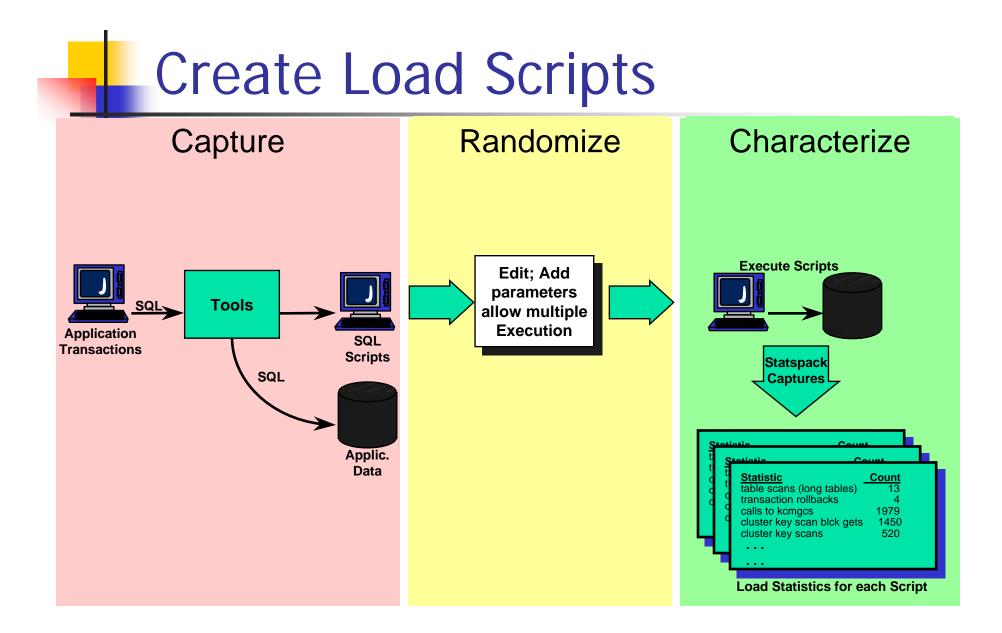

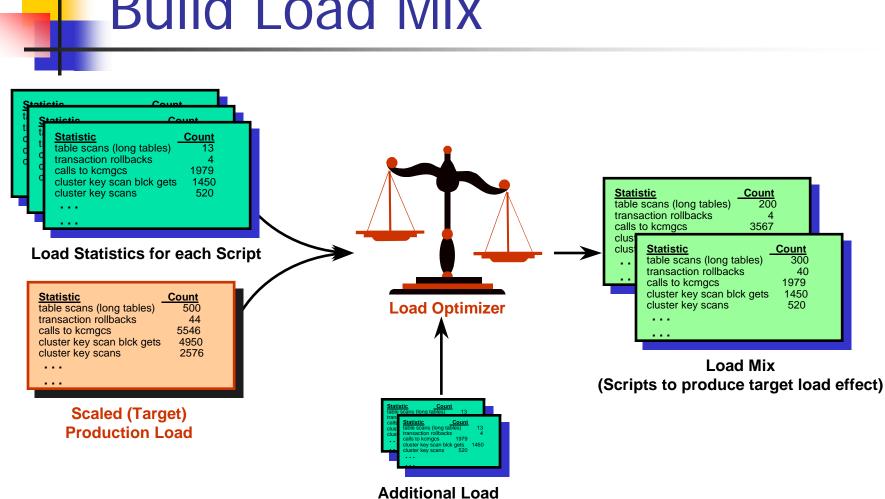

Data Server Load Method

Determine Target Load

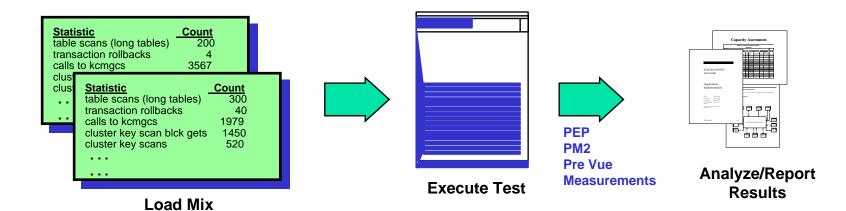

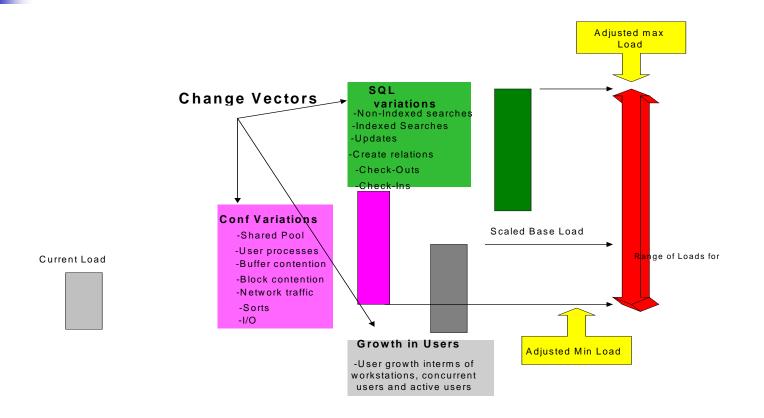

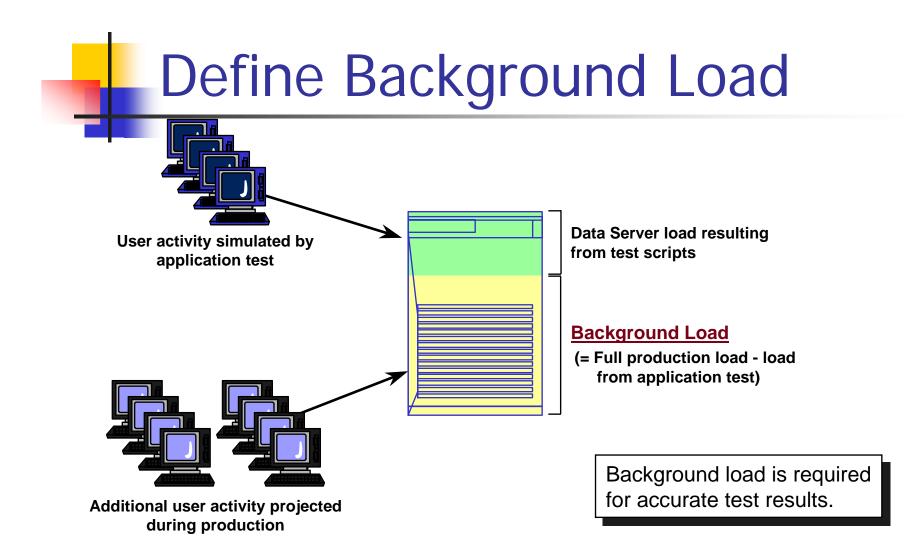

Build Load Mix

Execute Load & Analyze

ODSS Application Configuration and SQL variants

Example of Performance Analysis

Summary of performance analysis

$100\text{-}200\% \text{lo} \epsilon \ 200\text{-}300\% \text{lo} \epsilon \ 300\text{-}400\% \text{lo} \epsilon \ 100\text{-}300\% \text{lo} \epsilon \ 100\text{-}400\% \text{lo} a \text{d}$

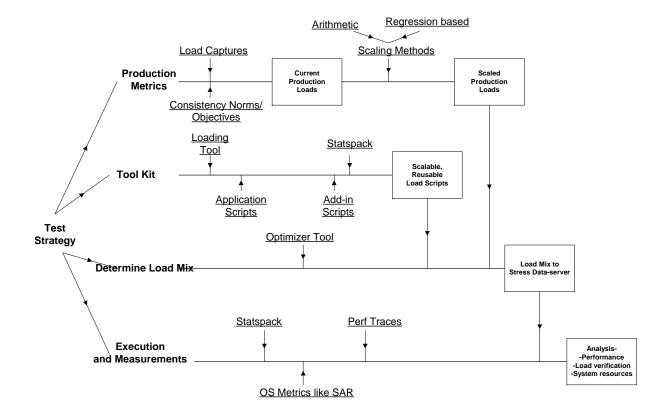

Long Running Queries	159%	194%	214%	308%	661%
Medium range Queries	125%	163%	113%	200%	229%
Short queries	113%	155%	115%	175%	202%

Performance Impact Analysis:

1. Long running queries show severe degradation 1t 300 and 400% loads

2. Medium range and short queries deteriorate severely during 300% load growth and remain relatively

Strategic Elements
